Lecture 6: Scoreboarding Example,
Tomasulo's Algorithm

Lecture Outline

- Scoreboarding Review (A.8)
- Tomasulo's Algorithm (3.1-3.3)
  - Dynamic Scheduling + Register Renaming
  - Example 1: Same code as last time
  - Example 2: Hardware Loop Unrolling
- Pointer-Based Renaming (MIPS R10000)

An aside…

- Interested in the real-world, business side of computer architecture?
- Bob Colwell (Chief Architect of Intel P6-core, used in PentiumPro, PII, PIII) gave a talk at Stanford recently.
- Technical architecture vs. marketing/management, many anecdotes

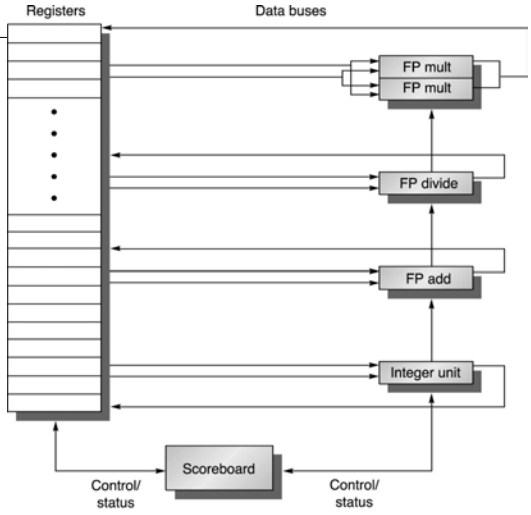
Scoreboarding

- Centralized scheme
  - No bypassing
  - WAR/WAW hazards are a problem
- Originally proposed in CDC6600 (S. Cray, 1964)



Scoreboarding Stages – Issue (Or Dispatch)

- Fetch – Same as before
- Issue (Check Structural Hazards)
  - If FU is free an no other active instruction has same destination register (WAW), then issue instruction
  - Do not issue until structural hazards cleared
  - Stalled instruction stay in I-Buffer
  - Size of buffer is also a structural Hazard
    - May have to stall Fetch if buffer fills
  - Note: Issue is In-Order, stalls stops younger instructions

Scoreboarding Stages – Read Operands (Or Issue!)

- Read Operands (Check Data Hazards)
  - Check scoreboard for whether source operands are available
  - Available?
    - No earlier issued active instructions will write register
    - No currently active FU is going to write it
  - Dynamically avoids RAW hazards

Scoreboarding Stages – Execution/Write Result

- Execution
  - Execute/Update scoreboard
- Write Result
  - Scoreboard checks for WAR stalls and stalls *completing* instruction, if necessary
  - Before, stalls only occur at the beginning of instructions, now it can be at the end as well
  - Can happen if:
    - Completing instruction *destination* register matches an older instruction that has not yet read its *source* operands

Scoreboarding Control Hardware

- Three main parts
  - Instruction Status Bits
    - Indicate which of the four stages instruction is in
  - Functional Unit Status Bits
    - Busy (In Use or not), Operation being Performed
    - Fi -- Destination Register, Fj, Fk, -- Source Registers
    - Qj, Qk – FU producing source regs Fj, Fk
    - Rj, Rk – Flags indicating when Fj, Fk are ready but not yet read
  - Register Result Status
    - Which FU will write each register

Scoreboarding Limitations

- Number and type of functional units
- Number of instruction buffer entries (scoreboard size)
- Amount of application ILP (RAW hazards)
- Presence of antidependencies (WAR) and output dependencies (WAW)
  - Inorder issue for WAW/Structural Hazards limits scheduler
  - WAR stalls are critical for loops (hardware loop unrolling)

Tomasulo's Approach

- Used in IBM 360/91 Machines (Late 60s)
- Similar to scoreboarding, but added renaming
- Key concept: Reservation Stations

- Very Important Topic
  - Scheduling ideas led to Alpha 21264, HP PA-8000, MIPS R10K, Pentium III, Pentium 4, PowerPC 604, etc…

Reservation Stations (RS)

- Distributed (rather than centralized) control scheme
  - Bypassing is allowed via Common Data Bus (CDB) to RS
  - Register Renaming eliminates WAR/WAW hazards
- Scoreboard/Instruction Buffer => Reservation Stations
  - Fetch and Buffer operands as soon as available
    - Eliminates need to always get values from registers at execute
  - Pending instructions designate reservation stations that will provide their inputs
  - Successive writes to a register cause only the last one to update the register

Register Renaming

- Compiler can eliminate some WAW/WAR "false" hazards, but not all
  - Not enough registers
  - Hazards across branches (common!) – can eliminate on taken, or fall through but not both
  - Hazards with itself -- dynamic loops (example later)
- Example (spill code causing "false hazards")

C = A + B
D = A - B

```
ADD   R3, R1, R2
SW    R3, 0(R4)
SUB   R3, R1, R2
```

Register Renaming

- Dynamically change register names to eliminate "false dependencies" (WAR/WAW hazards)
- Architectural registers: *Names* not Locations
  - Many more locations ("reservation stations" or "physical registers") than names ("logical or architectural registers")
  - Dynamically map names to locations

Register Renaming Example

Assume temporary registers S and T

```
DIV  F0, F2, F4          DIV  F0, F2, F4
ADD  F6, F0, F8          ADD  S, F0, F8
SW   F6, 0(R1)     →     SW   S, 0(R1)
SUB  F8, F10, F14        SUB  T, F10, F14
MUL  F6, F10, F8         MUL  F6, F10, T
```

Register Renaming with Tomasulo

- At instruction issue:
  - Register specifiers for source operands are renamed to the names of the reservation stations
  - Values can exist in reservation station or register file
    - To eliminate WARs, register file values are *copied* to reservation stations at issue
    - Other methods example use *pointer-based* renaming (map-table)
- Technique used in Pentium III, PowerPC604

Reservation Station Components

- Op: Operation to perform in the unit
- Qj, Qk: Reservation stations producing source registers (value to be written)
  - Note: No ready flags needed as in Scoreboard
  - Qj,Qk=0 => ready
  - Store buffers only have Qi for RS producing result
- Vj, Vk: Value of Source operands
  - Store buffers has V field, result to be stored
- Busy: Indicates reservation station or FU are occupied
- Register Result Status: Indicates which functional unit will write each register, if one exists. Blank when no pending instructions that will write that register.

Three Stages of Tomasulo Algorithm

1. Issue—get instruction from FP Op Queue

   If reservation station free (no structural hazard),
   control issues instr & sends operands (renames registers).

2. Execution—operate on operands (EX)

   When both operands ready then execute;
   if not ready, watch Common Data Bus for result

3. Write result—finish execution (WB)

   Write on Common Data Bus to all awaiting units;
   mark reservation station available

Data Buses in Tomasulo Algorithm

- Normal data bus: data + destination ("go to" bus)
- Common data bus: data + source ("come from" bus)
  - 64 bits of data + 4 bits of Functional Unit source address
  - Write if matches expected Functional Unit (produces result)
  - Does the broadcast

How can Tomasulo overlap iterations of loops?

- Register renaming
  - Multiple iterations use different physical destinations for registers (dynamic loop unrolling).
  - Replace static register names from code with dynamic register locations
  - Increases effective size of register file
  - Permit instruction issue to advance past integer control flow operations.
- Crucial: integer unit must "get ahead" of floating point unit so that we can issue multiple iterations

Tomasulo Loop Example

```
Loop:LD      F0   0    R1
     MULTD   F4   F0   F2
     SD      F4   0    R1
     SUBI    R1   R1   #8
     BNEZ    R1   Loop
```

- Multiply takes 4 clocks
- Assume first load takes 8 clocks (cache miss), second load takes 1 clock (hit)
- Will show clocks for SUBI, BNEZ
- Reality: integer instructions run ahead

Tomasulo Review

- Reservation Stations
  - Distribute RAW hazard detection
  - Renaming eliminates WAW hazards
  - Buffering values in Reservation Stations removes WARs
  - Tag match in CDB requires many associative compares
- Common Data Bus
  - Achilles heal of Tomasulo
  - Multiple writebacks (multiple CDBs) expensive
- Load/Store reordering
  - Load address compared with store address in store buffer

Tomasulo vs. Scoreboarding

1. No explicit checking for WAW or WAR hazards
2. CDB broadcasts results rather than waiting on registers
3. Loads/Store are treated like basic FUs
4. Distributed vs. Centralized control

Register Renaming: Pointer-Based

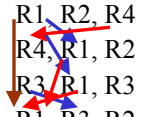
- MIPS R10K, Alpha 21264, Pentium 4, POWER4
- Mapper/Map Table: Hardware to hold these mappings
  - Register Writes: Allocate new location, note mapping in table
  - Register Reads: Look in map table, find location of most recent write
- Deallocate mappings when done

Register Renaming: Example

- Mapper/Map Table: Hardware to hold these mappings
  - Register Writes: Allocate new location, note mapping in table
  - Register Reads: Look in map table, find location of most recent write
- Deallocate mappings when done

- Assume
  - 4 Architected/Logical Registers (F1,F2,F3,F4) “names”
  - 8 Physical/Rename Registers (P1—P8) “locations”
- Code – Lots of Potential WAR/WAW, also RAWs

```
ADD   R1, R2, R4
SUB   R4, R1, R2
ADD   R3, R1, R3
ADD   R1, R3, R2
```



Register Renaming: Example

P5	P2	P3	P4
P5	P2	P3	P6

```
